

## 1. [MST, 16 points]

Each of the following algorithms takes a connected weighted graph  $G(V, E)$  as input, and returns a set of edges  $T$ . For each algorithm, either explain why  $T$  is a minimum spanning tree or give a counter-example.

a. MAYBE-MST-A( $G$ )

$T = \text{empty}$

for each edge  $e$ , taken in arbitrary order

if  $T \cup \{e\}$  has no cycles

$T = T \cup \{e\}$

return  $T$

b. MAYBE-MST-B( $G$ )

sort the edges into non-increasing order of edge weights  $w$

$T = E$

for each edge  $e$ , in non-increasing order by weight

if  $T - \{e\}$  is a connected graph

$T = T - \{e\}$

return  $T$

a.  $T$  is NOT a minimum spanning tree (MST)

$$T = \{5, 4, 3, 1\}; 5 + 4 + 3 + 1 = 13$$

$\Rightarrow$  NOT MST since  $13 > 10$

MST =  $\{1, 2, 3, 4\}$ ;  $1 + 2 + 3 + 4 = 10$   
 (with Prim's Algorithm)  $\text{visited} = \{D, E, B, A, C\}$   
 (start at D)

b.  $T$  is a MST because the extra edges are removed in non-increasing order; we preserve the edges with minimum weights

MST =  $\{1, 2, 3, 4\}$ ;  $1 + 2 + 3 + 4 = 10$   
 (Kruskal's Algorithm)  $\text{visited} = \{E, D, B, A, C\}$

$$T = \{7, 6, 5, 4, 3, 2, 1\}$$

$\downarrow$  remove 7 edge

$$= \{6, 5, 4, 3, 2, 1\}$$

$\downarrow$  remove 6 edge

$$= \{5, 4, 3, 2, 1\}$$

$\downarrow$  remove 5 edge

$$= \{4, 3, 2, 1\}; 4 + 3 + 2 + 1 = 10, \text{MST} \checkmark$$

removing any more edges results in an unconnected graph

2. [MST, 12 points]

Give an algorithm to find a maximum spanning tree in a connected undirected graph.

Apply a modified Kruskal's Algorithm.

Rather than sorting edges in nondecreasing order, sort in **non INCREASING** order.

Implement the rest of Kruskal's in the original way: add edges that do not form cycles until there are  $|V|-1$  edges ( $|V|$  is # of vertices).

3. [Single-Source Shortest Path, 12 points]

Design an efficient algorithm that outputs the overall number of paths that exist in a given directed acyclic graph. Analyze the runtime of your algorithm.

1. Topological Sort the graph

$\mathcal{O}(V+E)$

2. Create an array to store # of paths to each vertex

$\mathcal{O}(V)$

Initialize the first node's # of paths to one, and the rest to zero

3. Traverse the vertices in topological order, updating the # of paths array

$\mathcal{O}(V+E)$

For each vertex, add the # of paths to the current vertex to the # of paths of its neighbors

4. Simply index into the # of paths array for the desired destination node to output the overall # of paths  $\mathcal{O}(1)$

Total Runtime:  $\mathcal{O}(V+E)$

4. [Single source shortest path, 10 points]

Bellman Ford's shortest path algorithm has a runtime of  $\mathcal{O}(VE)$ . Explain why this is the case, and suggest a method of detecting whether the algorithm may stop early.

Bellman Ford has a runtime of  $\mathcal{O}(VE)$  because **each edge is relaxed  $V-1$  times ( $V$  asymptotically)**.

The algorithm may stop early if for a particular iteration, we **never update the distances to each vertex**.
